

Background

- Historically there has been a tendency for research to focus on “negative” impacts or outcomes for parents raising a child with a developmental disability (DD) such as stress, depression, divorce, etc.
- More recently, it has been recognized that parents may experience “positive” outcomes as well (such as increased sense of purpose in life, greater compassion)
- Negative and positive not opposite or mutually exclusive, although precise conceptualization of positive outcomes not clear or consistent in literature
- Research tends to show child characteristics, especially maladaptive behaviour, to influence negative outcomes, but unclear how related to positive
- Few studies examine both positive and negative outcomes simultaneously in terms of their relationship with child characteristics and other psychosocial predictors
- Few studies in Canadian samples
- Few studies in samples with severe DD

Theoretical Model

- Perry (2004) proposed a “dual outcome” model with domains of factors that may be important as predictors, mediators, or moderators of both parent outcomes in 6 domains (see above)

Purpose

- The GO4KIDDS initiative included two surveys about the health, well-being, and social inclusion of children with severe DDs in Canada, and the experience of their parents:
 - Basic Survey** – very brief measures of principal constructs
 - Extended Survey** – longer, more in depth, covering all domains of Perry (2004) model
 - In the current study, we explore the correlates and predictors of positive and negative parent impacts using the large, nationwide sample from the **Basic Survey**
- Hypotheses:**
- Positive and negative outcomes are independent
 - Child Characteristics related to negative outcomes; not to positive outcomes
 - Resources & Supports related to both, in opposite directions

Participants N=444

- parents/caregivers from all across Canada:

- 90% mothers
- age 24-65 (M=42)
- 75% married

Stressors

- Child age
- Diagnosis (ASD or not)
- Adaptive skills (GO4KIDDS submitted; 8 items; $\alpha = .87$)
- Maladaptive behaviour & mental health issues (4 items; $\alpha = .64$)

- children/adolescents with severe DDs

- 70% M
- age 3-21 (M=11)
- diagnosis (parent report): ID 45%, ASD 55%

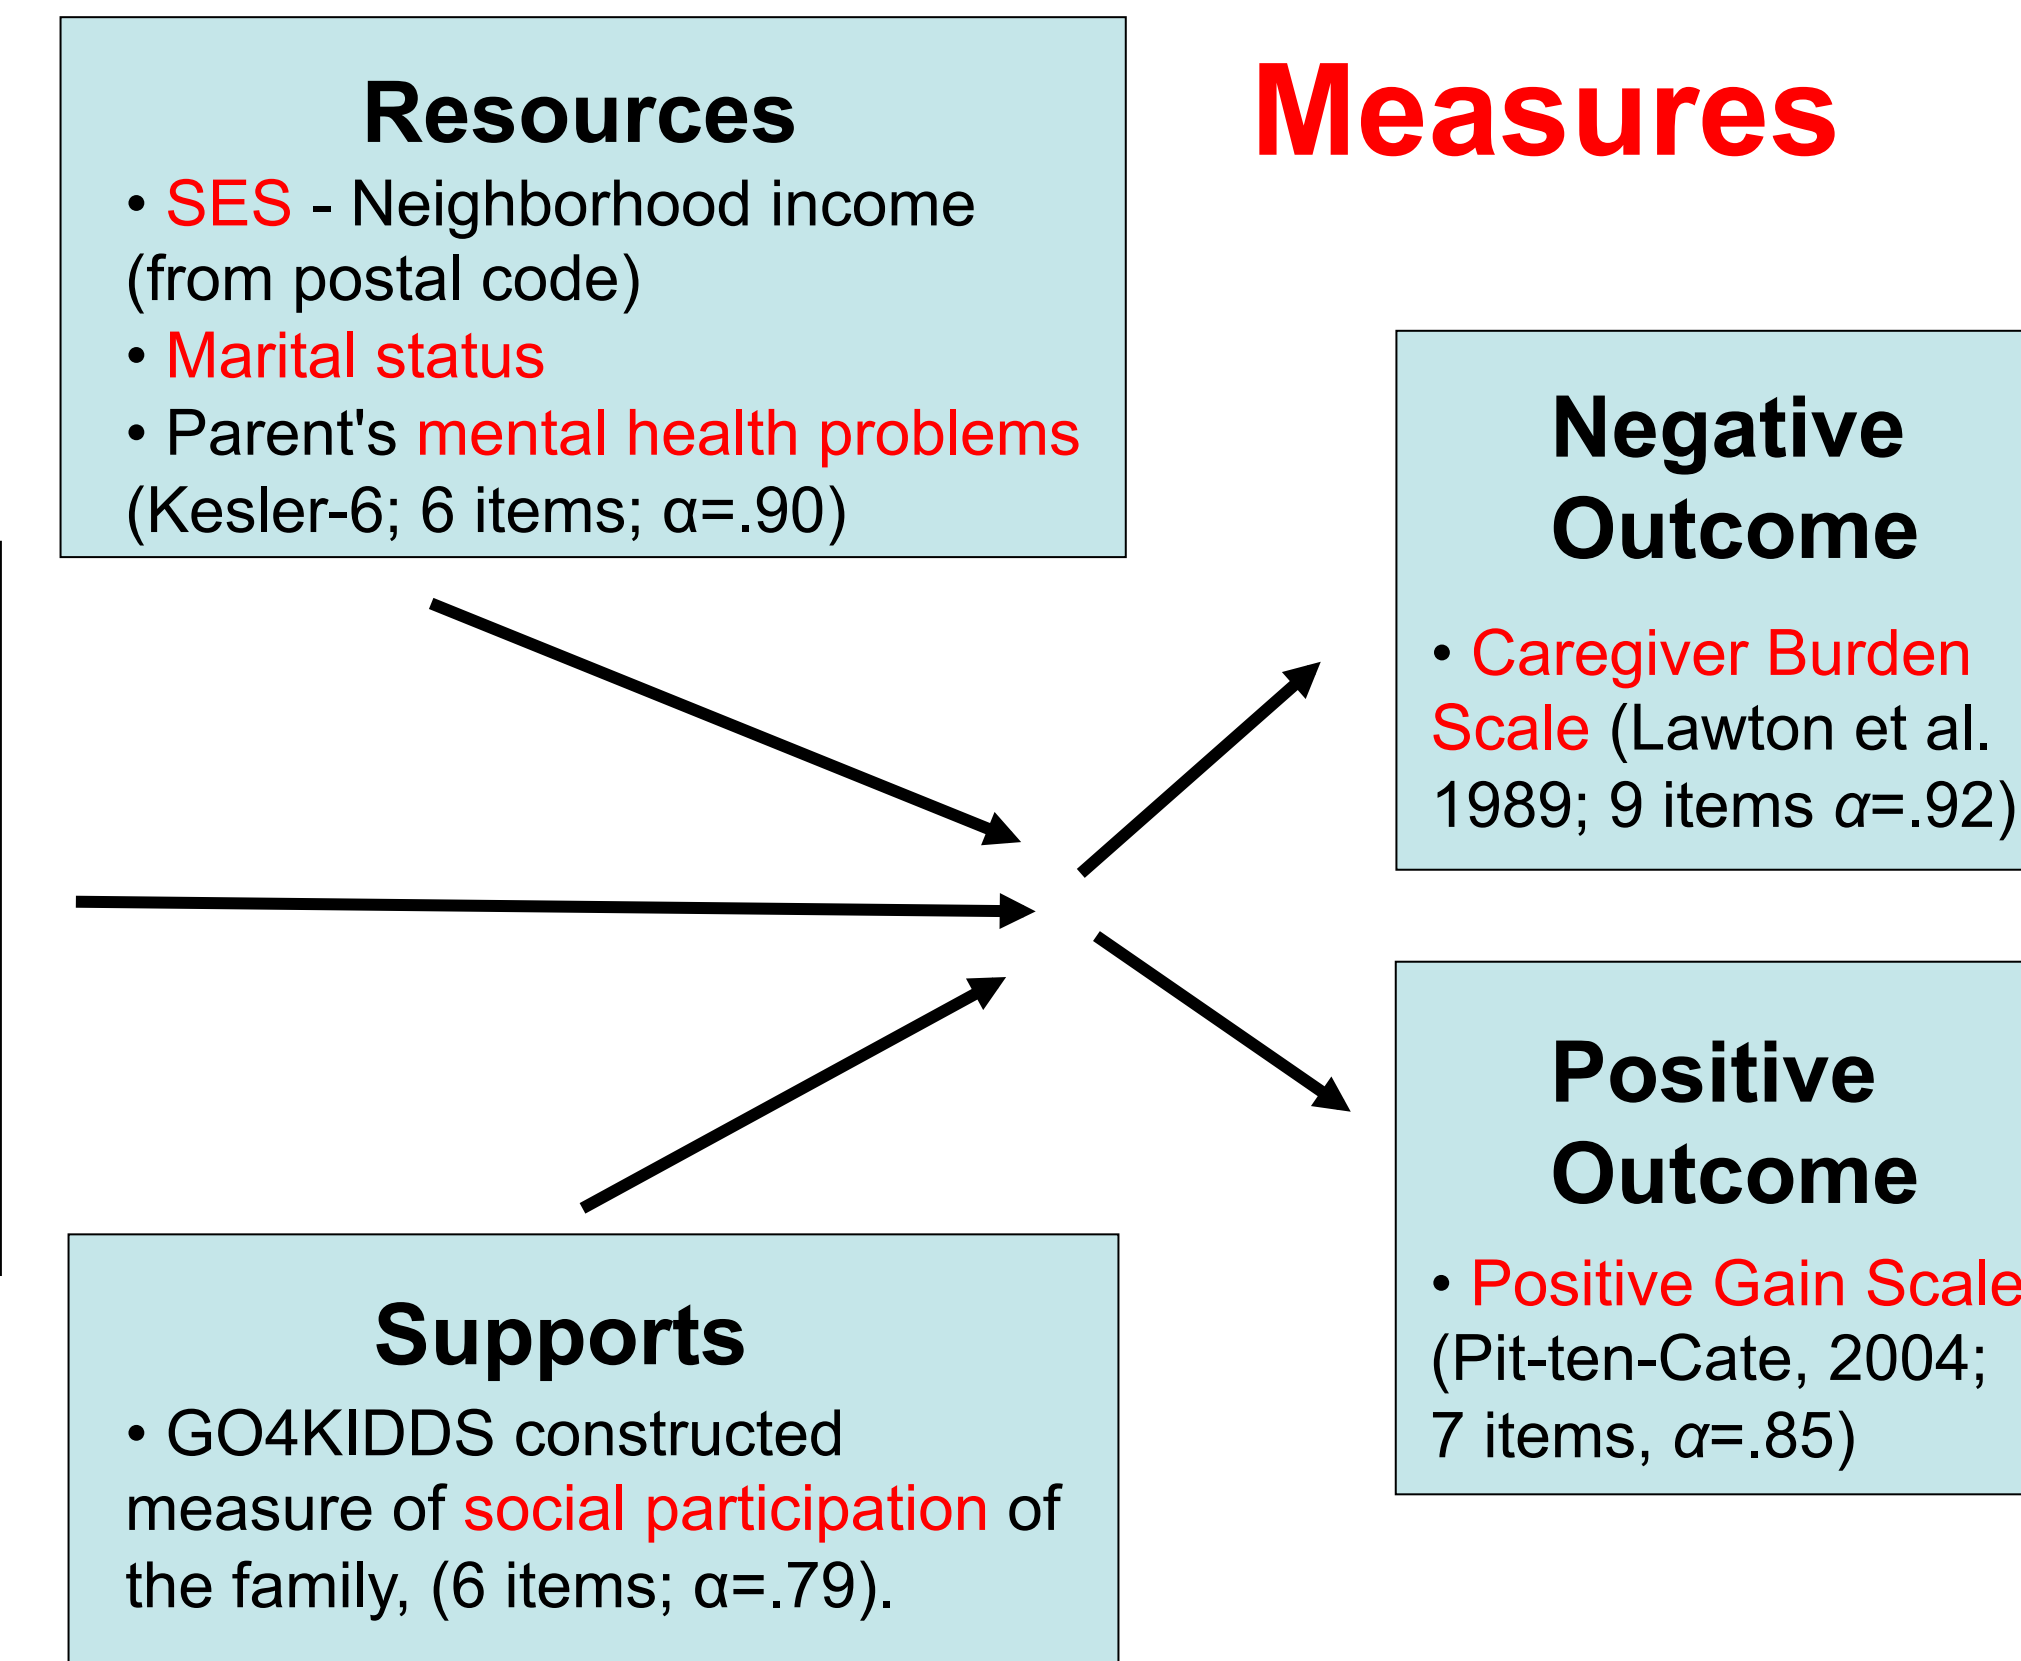

Table 1. Correlations of Predictors and Outcomes

	Strong Moderate Weak	Caregiver Burden <i>r</i>	Positive Gain <i>r</i>
Stressors	* $p < .01$		
Adaptive Behaviour		-.28*	.07
Maladaptive Behaviour		.40*	-.19*
Age		.07	-.15*
Diagnosis of ASD		.18*	.07
Resources & Supports			
Neighbourhood Income		.04	.04
Mental health problems		.59*	-.27*
Social participation		.47*	-.22*

Predictors of Positive Gain (Table 3 below)

- Child Characteristics account for only 6% of variance (younger → more positive outcomes)
- Resources & Supports account for only an additional 6% (lower mental health problems, greater social participation → more positive outcomes)
- Total variance accounted for = 12% (modest)

Table 3. Regression to predict Positive Gain

Step		Specific predictors	β	<i>p</i>
Stressors	$R^2 = .06$	Child age	-.16	.003
Resources & Supports	$\Delta R^2 = .06$	Mental health problems	-.19	.001
		Social participation	-.16	.04
Total	$R^2 = .12$	$F(8,343) = 5.90, p < .001$		

Results

Correlations (Table 1)

- The two outcomes had a weak inverse relationship ($r = -.26$)

Stressors (child characteristics) :

- Tended to be more strongly related to Burden than to Positive Gain, except for child's age

Resources and Supports:

- SES unrelated to both outcomes
- Other two variables related in opposite direction (sensible) but stronger relationship to Burden

Table 2. Regression to predict Caregiver Burden

Step		Specific predictors	β	<i>p</i>
Stressors	$R^2 = .23$	Child age	.12	.015
		Adaptive	-.26	<.001
		Maladaptive	.36	<.001
Resources & Supports	$\Delta R^2 = .25$	Mental health problems	.43	<.001
		Social participation	-.25	<.001
Total	$R^2 = .49$	$F(8,343) = 40.44, p < .001$		

Predictors of Caregiver Burden (Table 2 above)

- Child Characteristics accounted for 23% of variance (older, lower adaptive skills, higher maladaptive behaviour → more negative outcomes)
- Addition of Resources & Supports accounted for an additional 25% of variance (more mental health problems, lower social participation → more negative outcomes)
- Total variance accounted for = 49% (substantial)

Discussion

- Hypothesis 1. **Positive and negative outcomes independent?** We found weak negative correlation ($r = -.26$) but still suggests examining two outcomes separately
- Hypothesis 2. **Child Characteristics more related to negative than positive?** was generally supported:
 - in Regressions, child factors accounted for one quarter of the total variance vs only 6% for positive outcomes
 - child's age was the only child characteristic that was significantly related to both outcomes in regressions: parents of older children report greater Burden and lower Positive Gain – this has important clinical implications
 - although diagnosis of ASD (vs ID) was associated with greater burden in the zero-order correlations, it dropped out in the regressions, presumably because of common variance subsumed by maladaptive behaviour – so parents of children with ASD do not necessarily have different outcomes based on the diagnosis of ASD per se
- Hypothesis 3. **Resources and Supports important for both outcomes?** was supported:
 - both variables included (parent mental health problems and family social participation) were significant predictors (in opposite directions) of both outcomes
- In general, we can better account for negative outcomes vs. positive ones → future research challenge to understand positive outcomes better

Strengths: sample large and diverse, Canadian, severe DD

Limitations: sample is mostly mothers, volunteers, representative?, very brief measures, all self-report

- Several important constructs not measured (e.g., other life stress, family functioning, formal support)
- Directionality of these findings is uncertain (e.g., do mental health problems lead to or result from high Caregiver Burden?)

Next steps:

- Qualitative examination of responses to open ended questions (Luthra et al., RSIG poster)
- Replication with Extended Survey data – smaller sample but different outcome measures and more measures of other constructs in Perry (2004) model
